SOLUBLE  
MANNOSE RECEPTOR PEPTIDES

Background of the Invention

This invention relates to the general field of  
5 anti-microbial and anti-viral compounds, including  
diagnostic compounds, as well as to methods and reagents  
for making and using the compounds.

It is known to use as anti-microbial agents  
compounds that interfere with the metabolic processes of  
10 the infective cell. For example, antibacterial agents of  
the sulfonamide class, as structural analogs of  
p-aminobenzoic acid, block purine nucleotide synthesis in  
susceptible microorganisms, while penicillin prevents the  
completion of the final stages of cell wall biosynthesis.

15 A number of antiviral agents such as AZT and  
suramin achieve their effect by targeting the uniquely  
retroviral enzyme reverse transcriptase. AZT has been  
approved for treatment of patients with the Acquired  
Immune Deficiency Syndrome (AIDS), caused by the Human  
20 Immunodeficiency Virus Type 1 (HIV-1). Another anti-  
viral agent, the polyanionic compound dextran sulfate,  
blocks binding of virions to target cells. The soluble  
mannose-binding protein prevents infection of H9  
lymphoblasts by HIV-1 by binding to the high mannose  
25 glycans expressed on the envelope glycoprotein of the  
retrovirus (Ezekowitz et al., J. Exp. Med. 169:185-196,  
1989).

Summary

In one aspect, the invention features a soluble  
30 recombinant peptide comprising at least one (and  
preferably two, three or more) carbohydrate recognition  
domains derived from an extracellular portion of mannose  
receptor protein (MRP). The peptide is capable of  
specifically targeting cells expressing mannose, N-

- 2 -

acetylglucosamine, or fucose, by virtue of those carbohydrate recognition domain(s) (CRD). For example, the MRP-derived carbohydrate recognition domain can specifically bind eucaryotic or procaryotic pathogenic cells (e.g., bacteria, fungi, or viruses) having exposed configurations of the specified sugar moieties on their cell wall or on the envelope glycoprotein. In addition, a peptide containing the MRP-derived CRD can specifically target cancer cells which have any exposed mannose residues as a result of aberrant glycosylation. Peptides according to the invention offer a probe for such cells, or a tool for delivery of specific molecules (e.g., toxins or cell specific molecules such as the T-cell antigen, CD4) to those cells, or an in vivo marker for those cells to the immune system. The domain(s) are said to be MRP-derived in that they generally contain at least 150, or preferably 300 contiguous amino acids homologous to a sequence of one or more carbohydrate recognition domains of the mannose receptor protein, shown in Fig. 3.

The soluble peptide lacks the transmembrane and cytoplasmic regions of MRP. By peptide is meant a chain of about ten or more amino acids, including larger polypeptides and proteins, that are useful in this invention. The peptide may be glycosylated via O- or N-linkages. By recombinant peptide is meant a peptide that is expressed from engineered nucleic acid, defined below.

In another aspect, the invention features engineered nucleic acid (preferably cDNA) encoding such a soluble peptide. By engineered nucleic acid is meant nucleic acid removed from its natural environment (i.e., from naturally adjacent nucleic acid) by purification or recombinant DNA methodology; the term also includes synthetic nucleic acid or cDNA. This nucleic acid may be a fragment of DNA or RNA, it may be present in a vector system (e.g., a plasmid, cosmid or phage), or it may be

- 3 -

within the genome of an organism. In some cases, such nucleic acid is purified and includes a homogeneous preparation of desired nucleic acid.

In preferred embodiments, the peptide and nucleic acid encoding it are further characterized by at least 75% identity at the amino acid level to a sequence of at least 150, and preferably 300, contiguous amino acids of one or more carbohydrate recognition domains of mannose receptor protein most preferably the peptide includes the entire extracellular region of mannose receptor protein. In other preferred embodiments, the nucleic acid substantially corresponds to at least 450 contiguous bases of the nucleic acid encoding the soluble extracellular fragment of mannose receptor protein, deposited in the ATCC as ATCC No. 68430 and described herein as nucleotides 1-4212 of SEQ ID NO: 1; and the nucleic acid is ligated to nucleic acid encoding the toxic part of a toxin molecule (e.g., AZT, ricin, or cholera toxin), or to nucleic acid encoding a peptide capable of fixing complement. The hybrid peptides encoded by such ligated nucleic acid are especially useful for causing an effector molecule to be targeted to an undesired cell or other organism, such as a virus.

The peptides described above, and antibodies to those peptides, may be used in therapeutic or diagnostic agents. Preferably the peptide is purified, that is, the peptide is substantially separated from contaminating peptides. Most preferably it is provided as a homogenous preparation admixed in a carrier substance suitable for therapeutic use. By therapeutic agent is meant a substance useful for the treatment of a disease or disorder; by diagnostic agent is meant a substance relating to the detection of a disease or disorder.

In yet other aspects, the invention features methods for treating an animal, e.g., a human, infected

- 4 -

with a bacterium, fungus, or virus. (By bacterium, fungus, or virus is meant to include any type of undesired cell or other organism that is capable of causing an infection.) One such method includes

5 providing and administering a therapeutically effective amount of a therapeutic agent or peptide including a soluble extracellular portion of mannose receptor protein capable of specifically targeting cells expressing mannose, N-acetylglucosamine, or fucose. The therapeutic

10 agent or peptide causes direct inhibition of growth of the infective organism, or causes host defensive cells, e.g., macrophages, to be attracted to the pathogenic organisms which are thereby inactivated. Such inactivation may be aided by the presence of complement

15 which is fixed by the peptide. A therapeutically effective amount is that quantity which produces a significant physiological effect in the patient and is recognized by those of ordinary skill in the art to depend upon the size and weight of the animal as well as

20 other well known factors.

In preferred embodiments, the peptide is a therapeutically effective fragment of the soluble extracellular portion of mannose receptor protein; the peptide is able to inhibit (e.g., reduce or prevent)

25 growth of, or infection by, the bacterium, fungus, or virus, and is a peptide as described above. Most preferably, the animal is human; the infection is one that results in a bacteremia or local bacterial infection, parasitic infection, or fungal colonization,

30 and the route of administration is either intravenous, intramuscular, oral, or local, e.g., in the form of a powder, or lotion, preferably at 5-100  $\mu\text{g/ml}$ , more preferably at 25  $\mu\text{g/ml}$ ; or the virus is HIV or a related virus, and the peptide lowers the rate of infection of

35 eucaryotic cells by the virus; the protein or peptide is

- 5 -

provided at 1-500  $\mu\text{g/ml}$  (preferably 100-150  $\mu\text{g/ml}$ ) final concentration in human serum or tissue. Alternatively, lipid vesicles, or lysosomes, containing toxins or antibiotics are coated with the peptide and administered directly to the patient. Such lysosomes will be targeted to the infected area by the peptide and the content of the lysosomes released, thereby specifically retarding or preventing growth of the targeted cells or organisms in the targeted area.

10 In a related aspect, the invention features a coated catheter, useful for long-term administration of fluids to a patient. The catheter is coated with one of the above-described peptides, e.g., by impregnating the catheter material with the peptide. The peptide lowers  
15 the rate of bacterial, fungal or viral infection of the patient through the catheter.

In another aspect, the invention features a method for diagnosing infection by a bacterium, fungus or virus. The method includes detecting the serum level of a  
20 pathogen that expresses one of the target glycoproteins recognized by MRP, by measuring the amount of binding of a peptide according to the invention to a sample of the serum. The detected pathogen level reflects the infection of the patient. Preferably, the method  
25 features measuring the peptide by immunologic or fluorescent techniques.

In a related aspect, the invention features a purified antibody specifically recognizing a peptide according to the invention. The antibody is preferably  
30 provided as a homogeneous preparation of a monoclonal or polyclonal antibody. The antibody is useful for purification of the extracellular portion of mannose receptor protein or peptides thereof, according to the invention, and for diagnosis of infection as disclosed  
35 above.

- 6 -

In a final aspect, the invention features a purified soluble peptide comprising the extracellular portion of mannose receptor protein, said peptide lacking the mannose receptor protein transmembrane and cytoplasmic regions.

Other features and advantages of the invention will be apparent from the following description of the preferred embodiments thereof, and from the claims.

#### Brief Description of the Drawings

Fig. 1a shows the nucleotide base sequence and the corresponding amino acid sequence of the extracellular portion of the mannose receptor protein, described herein as nucleotides 1-4212 of SEQ ID NO: 1.

Fig. 1b shows the nucleotide base sequence and the corresponding amino acid sequence of the transmembrane and cytoplasmic portions of the mannose receptor protein, described herein as nucleotides 1-4212 of SEQ ID NO: 2.

Fig. 2 is a schematic diagram including the functional regions of the extracellular portion of the mannose receptor protein.

Fig. 3 shows the correspondance of the amino acid sequence of the various carbohydrate recognition domains of the mannose receptor, using the single letter amino acid code.

#### Description of the Preferred Embodiment

Soluble recombinant peptides derived from an extracellular portion of the mannose receptor that contains one or more carbohydrate recognition domains (CRDs) are able to recognize carbohydrates with a specificity comparable to that of the native membrane-bound mannose receptor. Such soluble mannose receptor peptides can be immobilized or attached to a portion of another molecule without losing effective carbohydrate recognition capacity.

- 7 -

Exposed sugars like mannose and N-acetylglucosamine are a feature of the cell walls of many pathogens, whereas higher organisms, including humans and animals, tend to have masked internal mannose residues that are not recognized by the mannose receptor. Therefore, soluble mannose receptor peptides according to the invention are useful in therapeutic agents in that they specifically bind mannose-rich pathogens, including bacteria, fungi, yeasts, parasites, or the envelope glycoproteins of certain viruses. Such peptides can also specifically target cancer cells having exposed mannose residues as a result of aberrant glycosylation. When such soluble peptides are attached to other entities such as macrophages or peptide portions that fix complement, or used as a tool for the delivery of specific molecules such as toxins or cell-specific agents to mannose-rich pathogens, the peptides can direct removal of such pathogens from the patient. The soluble peptides according to the invention are also useful as probes in diagnosis.

The amino acid sequence of the mannose receptor, from which peptides according to the invention are derived, is inferred from the cDNA sequence (Figs. 1a and 1b) and analyzed below:

Referring to Fig. 2, the first domain is comprised of 134 amino acids at the NH<sub>2</sub> terminus. Without being bound to any theory, it appears that this cysteine-rich region is not essential to mannose targeting according to the invention, and, therefore, it may be deleted without departing from the spirit of the invention. Preferred soluble peptides according to the invention, however, include this domain.

The second domain spans from residues 135-188. Without being bound to any theory, this domain appears to be related to fibronectin type II, and it may play a role

- 8 -

in interaction with the extracellular matrix and contribute to the spreading and adhesion of tissue macrophages expressing the full length receptor. As with the first domain, the second domain is not essential to the practice of the invention, but preferred peptides include it.

Carbohydrate recognition domains (CRDs) comprise the remainder of the extracellular portion of the receptor. Specifically, there are eight segments related to C-type carbohydrate recognition domains (CRDs) of animal lectins reported by Drickamer, J. Biol. Chem. 263:9557-9560 (1988). These CRDs are discussed in greater detail below, and they are central to the invention.

A transmembrane region and a COOH-terminal cytoplasmic domain are truncated from the receptor in peptides according to the invention to enhance solubility and facilitate therapeutic application of such peptides. Surprisingly, after truncation of the transmembrane and intracellular portions of the receptor, the molecule retains carbohydrate binding capacity effective for various purposes discussed elsewhere in this application.

Preferred peptides according to the invention include at least one or more, and preferably four or more, of the eight carbohydrate recognition domains (CRDs) depicted in Fig. 2. The sequences of the individual CRDs are shown in Fig. 3 with the numbering of the starting amino acid of each CRD keyed to the amino acid sequence of the entire soluble extracellular portion of the mannose receptor as shown in Fig. 1a, nucleotides 1-4212 of SEQ ID NO: 1.

Those skilled in the art will recognize that it is possible to vary the specific sequence of the soluble carbohydrate-targeting peptide being used, without deviating from the concept and spirit of the invention.

- 9 -

The entire extracellular portion of the mannose receptor, truncated to remove the transmembrane portion and the cytoplasmic tail of the full length receptor, is a preferred peptide, but CRD-containing fragments of the truncated receptor are also within the scope of the invention.

Not only does the invention cover CRD containing fragments of the truncated receptor, it also covers conservative mutations of the truncated receptor and its fragments. Preferably, a peptide according to the invention includes multiple (two or more and, preferably, four or more) CRDs of mannose receptor protein. Moreover, individual CRDs can be repeated to further increase the carbohydrate binding capacity of the peptide according to the invention. Merely by way of example, and not as a limitation, the peptide can include multiple copies of one or more of the specific CRDs of the mannose receptor, shown in Fig. 3.

Isolated nucleic acid encoding a CRD of mannose receptor protein is useful for producing recombinant peptide fragments of the protein. In addition, the nucleic acid can be modified by standard techniques in order to express the same or modified peptides; e.g., by conservative base substitution the nucleic acid can be modified and still encode the same amino acid sequence, or the nucleic acid can be modified to encode a conservative amino acid substitution, which will preserve the tertiary structure and the distribution of charged amino acids in the peptide.

We now describe a specific cDNA clone of the extracellular portion (ectodomain) of mannose receptor protein (MRP). The clone is described not only as a specific example of the invention but also as a starting material to obtain other peptides according to the invention, using methods of producing candidate peptides

- 10 -

and methods for screening such candidates for mannose affinity, as described below.

Example 1: Cloning of Full Length MRP and Processing of MRP cDNA to encode and express peptides of the invention

- 5           Sequences for probes were determined by obtaining sequence information from purified receptor. Receptor was purified from alveolar macrophages or human placenta as described (Lennartz et al., J. Biol. Chem. 262:9942, 1987).
- 10           Degenerate oligonucleotide probes were synthesized on a Dupont oligonucleotide synthesizer, purified by gel filtration, and labeled with <sup>32</sup>p-ATP and polynucleotide kinase. Radiolabeled probe was used to screen a pCDM8 placental cDNA library (gift of Dr. B. Seed, Harvard
- 15   Medical School) by colony hybridization. Twenty-five positive clones were isolated by two rounds of amplification and analyzed. The longest clone (3.3kb) was found upon analysis to contain sequences encoding a number of peptides that had been derived from the
- 20   placental mannose receptor (Taylor et al., J. Biol. Chem. 265:12156, 1990). This 3.3kb placental derived clone was radiolabeled and used as a probe to isolate the macrophage mannose receptor cDNAs from a 7 day macrophage cDNA library (Ezekowitz et al., J. Exp. Med., in press,
- 25   December, 1990). A 750bp cDNA derived from the 5' extent of the placental mannose receptor cDNA was utilized to isolate 5' clones from the macrophage library. A full-length cDNA was then assembled in a CDM8 expression vector.
- 30           The sequence of macrophage mannose receptor is identical to the placental form except for a C to T polymorphism at nucleotide 2284. The initial placental clone was sequenced by double stranded sequencing using a modified T7 polymerase, Sequenase® (U.S. Biochemical,
- 35   Cleveland, Ohio) based on the Sanger chain termination

- 11 -

method (Sanger et al., Proc. Natl. Acad. Sci., USA 74:5463, 1977). Specific oligonucleotides were synthesized and used as sequencing primers. For phage clones, 2 $\mu$ l of purified stock was annealed to  $\lambda$ GT11 primers from each of the arms and the taq polymerase amplified product obtained after 25 cycles (94°C, 30s denaturation, 55°C 30s annealing, and 72°C 3 minute extension) on a thermal cycler (Dorfman et al., Bio. Techniques, 7:568, 1989), and the products were gel purified by agarose gel electrophoresis. The purified products were digested with EcoRI, subcloned into a pUC-19 vector, and the nucleotide sequence determined as described above.

The encoded protein sequence deduced from the nucleotide sequence is shown in Figs. 1a and 1b (SEQ ID NO: 1). The open reading frame predicts a protein of 1438 amino acids which is consistent with the estimated molecular weight of the receptor polypeptide (150kD) after the N-linked sugars have been removed. (Lennartz et al., J. Biol. Chem. 264:2385, 1989; Taylor et al., J. Biol. Chem. 265:12156, 1990; Ezekowitz et al., J. Exp. Med., in press, December, 1990).

The features of the membrane bound mannose receptor protein are depicted in a schematic diagram (Fig. 2) and include (i) a typical hydrophobic signal peptide; (ii) a cysteine rich NH<sub>2</sub> terminal region; (iii) a fibronectin type II domain; (iv) eight carbohydrate recognition domains; (v) a hydrophobic transmembrane region; and (vi) a cytoplasmic tail. The NH<sub>2</sub> terminal amino acid is defined by an N-terminus peptide as Leu, which is preceded by Ala-Val-Leu, a typical recognition sequence for a signal peptidase (Von Heijne, Eur. J. Biochem. 133:17, 1983).

For encoding and expressing peptides of the invention, cDNA encoding the full length mannose receptor

- 12 -

protein (MRP) was first derived in a CDM8 plasmid expression vector as described above. A construct of the cDNA encoding soluble mannose receptor peptide was then prepared in a CDM8 plasmid by a multiple step procedure, as follows.

Referring to Figs. 1a and 1b, in the first step: an antisense primer was designed from a 3' end, at base pair 4169, to a 5' end, at base pair 4201, to contain a HpaI site. The sense primer was prepared from a 5' end at base pair 3475 and encompassed the NsiI site base pair 3510. The primers were annealed to full length mannose receptor cDNA, and a 726 base pair fragment was amplified using the polymerase chain reaction technique (PCR). The full length cDNA mannose receptor in CDM8 was then digested with NsiI and HpaI which released a fragment from the unique NsiI site in the cDNA to the HpaI site in the vector, thereby removing (see Figs. 1a and 2) the last three amino acids of the ectodomain, the entire transmembrane region, the entire cytoplasmic domain, and some vector sequence. This fragment was replaced with the 726 bp PCR fragment, thereby creating a clone (SMR), confirmed by sequence analysis, which contained cDNA encoding the signal peptide and the entire ectodomain of the mannose receptor (except for the last three amino acids). This clone is capable of generating a soluble mannose receptor peptide. This construct can be transfected stably or transiently into a mammalian expression system, and the soluble receptor peptide expressed is secreted into the medium.

From this plasmid, which has been deposited in the ATCC as ATCC No. 68430, a series of truncated forms of soluble mannose receptor peptide containing various numbers of carbohydrate recognition domains can be constructed by standard molecular biological techniques, either by using the polymerase chain reaction or

- 13 -

convenient restriction enzyme sites to create molecules that can be secreted. Alternatively, standard molecular biological techniques may be used to isolate other nucleic acid (especially cDNA) clones encoding the  
5 extracellular portion of the mannose receptor protein by procedures analogous to those described above.

Expression vectors suitable for peptide expression also include standard bacterial, yeast, and viral expression vectors, as well as eucaryotic vectors. Those  
10 skilled in the art will realize that such vectors generally are suitable for expressing peptides of the invention.

Expression of soluble human mannose receptor peptides by these vectors and organisms can be followed  
15 using a mannan affinity column such as sepharose-mannose. The column is first contacted with the expressed material. Peptides able to recognize and bind mannose are bound to the mannose-sepharose matrix, eluted with 50mM Tris/10M EDTA, and identified using 8%  
20 polyacrylamide gels (with Laemmli buffers, Nature 227:600, 1970). Those clones which produce peptides able to bind to such a column are among those useful in this invention.

#### USE OF THE PEPTIDES

25 Soluble mannose receptor peptides expressed as described above are useful for specifically targeting (or specifically recognizing) cells expressing carbohydrates such as mannose, N-acetylglucosamine, or fucose on their surface. Thus these peptides are useful in agents for  
30 diagnosing or treating infection by a wide variety of pathogenic organisms, e.g., Leishmania proamastigotes, Pneumocystis carinii, Candida albicans, Microbacteria tuberculosis (and other atypical mycobacteria), Human Immunodeficiency Virus Type 1 (HIV-1) or influenza virus.  
35 Such agents are also useful for treating opportunistic

- 14 -

infections such as those that arise in patients with cancer, patients undergoing chemotherapy or bone marrow transplants, or patients suffering from congenital or acquired immune deficiency diseases, such as AIDS. In addition, such agents can specifically target cancer cells having exposed mannose residues as a result of aberrant glycosylation.

For non-viral pathogens, removal by host defense mechanisms is achieved by directing attachment of a soluble mannose receptor peptide, in conjunction with the cell attachment site of a receptor such as the mannose-binding protein, to the surface of phagocytic cells, thereby enhancing the clearance of the pathogens from the circulation by causing the phagocytes to recognize the pathogens. For viruses which express mannose-rich glycoproteins, direct inactivation of the virus and viral infected cells is accomplished by attaching toxins, such as ricin, cholera, diphtheria, or pertussis, or antimetabolic drugs, such as AZT, to a therapeutic soluble mannose receptor peptide. The hybrid peptide thus formed can serve to kill or inhibit growth of the target cell, such as HIV.

To form such hybrid peptides, nucleic acid encoding such toxins can be ligated by well known techniques to nucleic acid encoding a soluble mannose receptor peptide according to the invention, and the fused nucleic acid can be expressed as a single entity to form a hybrid peptide (for example, as described by Murphy, U.S. Patent No. 4,675,383, hereby incorporated by reference). (By ligated is meant linked enzymatically or chemically to form a single nucleic acid entity.) Alternatively, the two peptides can be synthesized separately and linked chemically (for example, as described by Ross, U.S. Patent No. 4,275,000, hereby incorporated by reference).

- 15 -

Alternatively, nucleic acid encoding a complement-fixing region, e.g., the complement-fixing region of the immunoglobulin heavy chain or of the mannose-binding protein, can be engineered by standard techniques to form a hybrid molecule with nucleic acid encoding a soluble mannose receptor protein. The expression product of such nucleic acid can be used to target cells with exposed surface carbohydrate moieties and then to interact with complement components and activate complement. Activated complement will then stimulate binding of macrophages to the targeted pathogenic cells and their subsequent ingestion by the macrophages.

Example 2: Preparation  
of a fusion protein

A soluble mannose receptor peptide-immunoglobulin fusion protein can be prepared by digesting cDNA encoding soluble mannose receptor peptide and inserting an oligonucleotide linker (e.g., a BamH1 linker). The resulting plasmid can be digested with BamH1, and the portion encoding the entire extracellular domain can be ligated to the synthetic splice donor sequence of an immunoglobulin (e.g., human IgG1) expression plasmid (Aruffo et al., Cell 61:1303-1313, 1990). Such expression vectors contain in their 3' region the immunoglobulin heavy chain constant regions two and three, which have the capacity to fix complement. A fusion protein expressed from such a fused cDNA sequence would contain a complement-fixing region at the 3' end of a soluble mannose receptor peptide.

In another construct, cDNA encoding an immunoglobulin signal peptide fused to the NH<sub>2</sub> terminal region, cell-attachment domain, and complement-fixing region of the mannose-binding protein (Ezekowitz, International Patent Application No. WO 89/01519, February 23, 1989) can be engineered to replace the

- 16 -

cysteine-rich and fibronectin binding domains of a soluble mannose receptor peptide. The fusion protein expressed from such a cDNA sequence would contain a complement-fixing region in the amino terminal portion of the molecule, preceding the carbohydrate recognition domains.

Soluble mannose receptor peptides according to the invention may be administered by routine methods in pharmaceutically acceptable carrier substances, i.e., inert substances suitable for pharmaceutical use such as the dispensing of drugs or medicine. For example, they can be administered in an aerosol form to treat, e.g., *Pneumocystis carinii*. Alternatively, they may be administered orally or parenterally, e.g., they can be injected directly into the blood stream of an animal, especially humans, to a level of between 1-500  $\mu\text{g/ml}$  serum (most preferably, 100-150  $\mu\text{g/ml}$ ) final concentration, and this dose repeated to maintain this level. The peptides can be administered prophylactically or after infection.

In a specific prophylactic use, soluble mannose receptor peptides may be used to coat intravenous or urethral catheters (e.g., by chemical impregnation of the catheter material with the peptide) to prevent infection in immunocompromised patients (e.g., cancer patients subjected to long term intravenous chemotherapy). Such catheters will bind infective organisms and prevent their entry into the patient.

In a specific therapeutic use, the soluble mannose receptor peptide may be applied topically in powder or lotion form (at a concentration of between 56-100  $\mu\text{g/ml}$ ), for example, to treat local infections, such as bacterial infection, yeast infection, or infection with Trichophyton, which causes athlete's foot.

- 17 -

Soluble mannose receptor peptides can also be used as a diagnostic tool, e.g., for the diagnosis of fungal diseases. Fungi infecting an animal will shed a mannose-rich polysaccharide into the serum. A sample of serum from a patient (e.g., 100 $\mu$ l) can be analyzed with fluorescently-labelled soluble mannose receptor peptide to observe binding to the fungal polysaccharide coat, and the degree of binding can be related to the degree of fungal infection remaining following a course of treatment. In an alternative diagnostic method, the degree of binding of the soluble mannose receptor peptide can be detected by using a labelled antibody that specifically recognizes the peptide. Appropriate subsequent treatment can be planned accordingly.

#### 15 Other Embodiments

As described above, the invention generally features peptides that include a MRP-derived carbohydrate recognition domain. The genetic material encoding soluble mannose receptor peptide (deposited as described above as ATCC No. 68430) can be used to generate a large number of recombinant peptides by fragmenting the full-length nucleic acid and expressing candidate fragments. Alternatively, as described above, standard molecular biological techniques may be used to isolate other nucleic acid (especially cDNA) clones encoding soluble mannose receptor peptides. These clones can also be used to express candidate fragment peptides. As described, preferred fragments are those containing multiple CRDs. Various assays may be used to determine whether a particular candidate peptide has carbohydrate recognition ability.

In addition to the affinity column chromatographic assay described above, another assay invokes binding and uptake of I<sup>125</sup>-labeled mannose-BSA. Specifically, mannose-BSA (EY Labs, CA) is radiolabeled as described

- 18 -

(Ezekowitz et al., J. Exp. Med. 154:60, 1981), and binding and uptake of radiolabeled ligand is performed on COS-I cells transfected with cloned cDNA encoding the candidate peptide. COS-I cells transfected with CD64  
5 serve as controls, and thioglycollate elicited mouse peritoneal macrophages serve as a positive control.

Another assay utilizes antibody that specifically recognizes a soluble mannose receptor peptide. The antibody may be linked with a fluorescent tag and  
10 antibody-peptide binding identified flow cytometrically. Alternatively, the antibody may be immobilized for assay use or employed in an enzyme linked immunosorbent assay or ELISA test.

#### Deposits

15 Plasmid SMR, in CDM8 in E-coli strain MC1061/P3, was deposited on Oct. 2, 1990, with the American Type Culture Collection (ATCC) as ATCC No. 68430.

Applicant's assignee, Children's Medical Center Corporation, represents that the ATCC is a depository  
20 affording permanence of the deposit and ready accessibility thereto by the public if a patent is granted. All restrictions on the availability to the public of the material so deposited will be irrevocably removed upon the granting of a patent. The material will  
25 be available during the pendency of the patent application to one determined by the Commissioner to be entitled thereto under 37 CFR 1.14 and 35 USC 122. The deposited material will be maintained with all the care necessary to keep it viable and uncontaminated for a  
30 period of at least five years after the most recent request for the furnishing of a sample of the deposited microorganism, and in any case, for a period of at least thirty (30) years after the date of deposit or for the enforceable life of the patent, whichever period is  
35 longer. Applicant's assignee acknowledges its duty to

- 19 -

replace the deposit should the depository be unable to furnish a sample when requested due to the condition of the deposit.

SEQUENCE LISTING

## (1) GENERAL INFORMATION:

(i) APPLICANT: Ezekowitz, Raymond Alan Brian

(ii) TITLE OF INVENTION: SOLUBLE MANNANOSE RECEPTOR PEPTIDES

5 (iii) NUMBER OF SEQUENCES: 1

(iv) CORRESPONDENCE ADDRESS:

10 (A) ADDRESSEE: Fish & Richardson  
(B) STREET: One Financial Center  
(C) CITY: Boston  
(D) STATE: Massachusetts  
(E) COUNTRY: U.S.A.  
(F) ZIP CODE: 02111-2658

(v) COMPUTER READABLE FORM:

15 (A) MEDIUM TYPE: 3.5" Diskette, 1.44 Mb storage  
(B) COMPUTER: IBM PS/2 Model 502 or 55SX  
(C) OPERATING SYSTEM: IBM P.C. DOS (Version 3.30)  
(D) SOFTWARE: WordPerfect (Version 5.0)

(vi) CURRENT APPLICATION DATA:

20 (A) APPLICATION NUMBER:  
(B) FILING DATE:  
(C) CLASSIFICATION:

(vii) PRIOR APPLICATION DATA:

25 Prior applications total,  
including application  
described below: 0

(A) APPLICATION NUMBER: 0  
(B) FILING DATE: 0

(viii) ATTORNEY/AGENT INFORMATION:

30 (A) NAME: Freeman, John W.  
(B) REGISTRATION NUMBER: 29,066  
(C) REFERENCE/DOCKET NUMBER: 00108-032001

(ix) TELECOMMUNICATION INFORMATION:

35 (A) TELEPHONE: (617) 542-5070  
(B) TELEFAX: (617) 542-8906  
(C) TELEX: 200154

## (2) INFORMATION FOR SEQUENCE IDENTIFICATION NUMBER: 1

## (i) SEQUENCE CHARACTERISTICS:

40 (A) LENGTH: 5145 base pairs  
(B) TYPE: nucleic acid  
(C) STRANDEDNESS: single  
(D) TOPOLOGY: linear

## (ii) SEQUENCE DESCRIPTION: SEQ ID NO. 1:

- 28 -

What is claimed is:

- 1           1. A soluble recombinant peptide comprising at  
2 least one carbohydrate recognition domain, derived from an  
3 extracellular portion of mannose receptor protein, said  
4 peptide lacking the mannose receptor protein transmembrane  
5 and cytoplasmic regions, said peptide being capable of  
6 specifically targeting cells expressing mannose, N-  
7 acetylglucosamine, or fucose.
- 1           2. The peptide of claim 1 comprising a sequence  
2 with greater than 75% homology to a fragment of at least 150  
3 contiguous amino acids of mannose receptor protein.
- 1           3. The peptide of claim 1 comprising at least 150  
2 contiguous amino acids of mannose receptor protein.
- 1           4. The peptide of claim 1 comprising a sequence  
2 with greater than 75% homology to a fragment of at least 300  
3 contiguous amino acids of mannose receptor protein.
- 1           5. The peptide of claim 1 comprising at least 300  
2 contiguous amino acids of mannose receptor protein.
- 1           6. The peptide of claim 1 comprising at least one  
2 complete carbohydrate recognition domain from mannose  
3 receptor protein, shown in Fig. 3.
- 1           7. The peptide of claim 1 comprising at least two  
2 complete carbohydrate recognition domains from mannose  
3 receptor protein, shown in Fig. 3.

- 29 -

1           8. The peptide of claim 1 comprising at least two  
2 copies of a carbohydrate recognition domain from mannose  
3 reception protein, shown in Fig. 3.

1           9. The peptide of claim 1 further comprising a  
2 segment capable of fixing complement.

1           10. The peptide of claim 9 wherein said peptide  
2 comprises a complement-fixing region of immunoglobulin heavy  
3 chain.

1           11. The peptide of claim 1 further comprising a  
2 cytotoxin.

1           12. The peptide of claim 11 wherein said cytotoxin  
2 is AZT, ricin, pertussis, or cholera toxin.

1           13. Engineered nucleic acid encoding the peptide of  
2 claim 1.

1           14. The engineered nucleic acid of claim 13 wherein  
2 said nucleic acid is cDNA.

1           15. A nucleic acid fragment substantially  
2 corresponding to at least 450 contiguous bases of the  
3 nucleic acid encoding the soluble extracellular fragment of  
4 mannose receptor protein (SEQ ID NO: 1), deposited in the  
5 ATCC as ATCC No. 68430, said fragment encoding a soluble  
6 peptide capable of specifically targeting cells expressing  
7 mannose, N-acetylglucosamine, or fucose.

1           16. Engineered nucleic acid substantially  
2 corresponding to the nucleic acid encoding the soluble

- 30 -

3 extracellular fragment of mannose receptor protein (SEQ ID  
4 NO: 1), deposited in the ATCC as ATCC No. 68430.

1 17. An expression vector comprising the engineered  
2 nucleic acid of claim 13.

1 18. A recombinant cell comprising the engineered  
2 nucleic acid of claim 13.

1 19. A therapeutic agent comprising a  
2 therapeutically effective amount of the peptide of claim 1  
3 administered in a pharmaceutically acceptable carrier  
4 substance.

1 20. The therapeutic agent of claim 19 comprising a  
2 lyposome coated with the soluble peptide.

1 21. A method for treating an animal infected with a  
2 bacterium, a fungus, or a virus, said method comprising the  
3 steps of  
4 providing the therapeutic agent of claim 19, and  
5 administering to the animal a therapeutically  
6 effective amount of said agent.

1 22. The method of claim 21 wherein said animal is  
2 human.

1 23. The method of claim 22 wherein said peptide is  
2 administered by application of a powder or a lotion  
3 comprising said peptide to the foot.

- 31 -

1           24. The method of claim 21 wherein said agent  
2 lowers the level of infection of eucaryotic cells by said  
3 bacterium, fungus, or virus.

1           25. A purified antibody specifically recognizing  
2 the peptide of claim 1.

1           26. A method for diagnosing, in an animal, an  
2 infection by a bacterium, a fungus, or a virus, said method  
3 comprising the steps of  
4           providing a sample of serum from the animal,  
5           contacting said serum with an effective amount of  
6 the peptide of claim 1, and  
7           measuring the amount of binding of said peptide to  
8 said serum sample.

1           27. The method of claim 26 wherein said animal is  
2 human and said infection is by a fungus.

1           28. The method of claim 26 wherein said measuring  
2 step comprises determining the amount of binding of an  
3 antibody specific for said peptide to a serum sample  
4 containing said peptide.

1           29. The method of claim 26 wherein said measuring  
2 step comprises fluorescence detection.

1           30. A purified soluble peptide comprising the  
2 extracellular portion of mannose receptor protein, said  
3 peptide lacking the mannose receptor protein transmembrane  
4 and cytoplasmic regions.

112
